# Singular star-exponential functions 

Hideki Omori and Takao Kobayashi

(Received November 12, 2001)

#### Abstract

The $*$-exponential function $e_{*}^{t i e^{a v} * u}$ is defined in a transcendently extended Weyl algebra. In the Weyl ordering expression, this is given as the real analytic solution in $t$ of $$
\begin{aligned} \partial_{t} F_{t}(u, v) & =i e^{a v}\left\{\left(u+\frac{\hbar i a}{2}\right) F_{t}\left(u+\frac{\hbar i a}{2}, v\right)-\frac{\hbar i}{2} \partial_{v} F_{t}\left(u+\frac{\hbar i a}{2}, v\right)\right\}, \\ F_{0}(u, v) & =1 \end{aligned}
$$

For generic initial functions, this equation can be solved for all $t$, but the uniqueness holds only for one direction.

Key words and phrases. Weyl algebra, star product, differential-difference equation.

## §1. Introduction

In this paper, we treat the Weyl algebra $W_{\hbar}$ generated over $\mathbb{C}$ by two elements $u, v . W_{\hbar}$ is the associative algebra with the fundamental relation $u * v-v * u=$ $-\hbar i$ where $\hbar$ is a positive constant.

In the Weyl ordering expression (cf. [9]), the Weyl algebra is understood as the space of polynomials with the Moyal product as follows:

$$
\begin{align*}
f(u, v) * g(u, v) & =f \exp \left\{\frac{\hbar i}{2} \overleftarrow{\partial_{v}} \dot{\wedge} \overrightarrow{\partial_{u}}\right\} g \\
& =\sum_{n=0}^{\infty} \frac{1}{n!}\left(\frac{\hbar i}{2}\right)^{n} \sum_{k=0}^{n}(-1)^{k}\binom{n}{k}\left(\partial_{v}^{n-k} \partial_{u}^{k} f\right)\left(\partial_{u}^{n-k} \partial_{v}^{k} g\right) \tag{1.1}
\end{align*}
$$

where $\overleftarrow{\partial_{v}} \wedge \overrightarrow{\partial_{u}}=\overleftarrow{\partial_{v}} \cdot \overrightarrow{\partial_{u}}-\overleftarrow{\partial_{u}} \cdot \overrightarrow{\partial_{v}}$, and the arrow indicates to which side the operator acts. This product formula yields $u * v-v * u=-\hbar i$, and hence
defines the Weyl algebra. The usual commutative product in the polynomial algebra plays only the supplementary role to write elements in a unique way.

Using this concrete product formula (1.1), we can extend the product $*$ as follows: Let $C^{\infty}(U)$ be the space of all $C^{\infty}$-functions on an open subset $U$ of the real 2-plane $\mathbb{R}^{2}$ with the $C^{\infty}$-topology.

- $f * g$ is defined, if one of $f, g$ is a polynomial.
- The associativity $f *(g * h)=(f * g) * h$ holds if two of $f, g, h$ are polynomials.
- If $p$ is a polynomial, then $p *$ and $* p$ are continuous linear mapping of $C^{\infty}(U)$ into itself.

Remark that such extension can be considered also for entire functions $\operatorname{Hol}\left(\mathbb{C}^{2}\right)$ with compact open topology, instead of $C^{\infty}(U)$.

In such an extended system, which will be called a $\mathbb{C}[u, v]$-module, the first task we should do is to fix product formula of several transcendental functions, and to determine exponential functions of several elements with respect to the product $*$. Several results are already given in [10] for the $*$-exponential functions of quadratic forms.

If we change variables $u, v$ by a transformation $\varphi$ given as follows:

$$
\binom{u^{\prime}}{v^{\prime}}=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right)\binom{u}{v}, \quad a d-b c=1,
$$

then we see $\left[u^{\prime}, v^{\prime}\right]=-\hbar i$ and $\left(\varphi^{*} f\right) *\left(\varphi^{*} g\right)=\varphi^{*}(f * g)$, if the product $f * g$ is defined. This is the most useful property of the Moyal product formula.

We call $(f, g)$ a quantum canonical conjugate pair, if $[f, g]=-\hbar i$ holds. $\left(u^{\prime}, v^{\prime}\right)$ is a quantum canonical conjugate pair which is linearly related to the original $(u, v)$, but there are a lot of quantum canonical conjugate pair $(f, g)$ which relates transcendentally to the original $(u, v)$. For instance, $\left(u^{\prime}, v^{\prime}\right)=$ $\left(\frac{u}{v}, \frac{1}{2} v^{2}\right)$ is a quantum canonical conjugate pair, treated in [12] and [8].

In this paper, we treat a quantum canonical conjugate pair $\left(e^{a v} * u,-\frac{1}{a} e^{-a v}\right)$ for $a>0$. We can easily check $\left[e^{a v} * u,-\frac{1}{a} e^{-a v}\right]=-\hbar i$ by a direct calculation using the Moyal product formula (1.1).

By the Moyal product formula, we see easily that $u * f(u, v)=u f(u, v)-$ $\frac{\hbar i}{2} \partial_{v} f(u, v)$ and

$$
e^{a v} * f(u, v)=e^{a v} \sum_{k} \frac{1}{k!}\left(\frac{\hbar i a}{2}\right)^{k}\left(\partial_{u}\right)^{k} f(u, v) .
$$

Since the above sum is the Taylor expansion of $f\left(u+\frac{\hbar i a}{2}, v\right)$, we extend the *-product by $e^{a v}$ as follows:

$$
e^{a v} * f(u, v)=e^{a v} f\left(u+\frac{\hbar i a}{2}, v\right)
$$

and

$$
f(u, v) * e^{a v}=e^{a v} f\left(u-\frac{\hbar i a}{2}, v\right)
$$

by a similar reasoning. Of course we assume that $e^{a v} * f(u, v)$ is well defined if and only if $f(u, v)$ is a function such that $f\left(u+\frac{\hbar i a}{2}, v\right)$ is well defined.

To define the $*$-exponential function $e_{*}^{t i e^{a v} * u}$, we consider the linear equation

$$
\left\{\begin{array} { r l } 
{ \frac { d } { d t } L _ { t } } & { = ( i e ^ { a v } * u ) * L _ { t } , }  \tag{1.2}\\
{ L _ { 0 } } & { = g ( u , v ) , }
\end{array} \quad \text { resp. } \quad \left\{\begin{array}{rl}
\frac{d}{d t} R_{t} & =R_{t} *\left(i e^{a v} * u\right), \\
R_{0} & =g(u, v)
\end{array}\right.\right.
$$

We call this the left (resp. right) equation.
Remark that if we set $\mu=e^{a v} * u$ and $\nu=-\frac{1}{a} e^{-a v}$, then $\mu, \nu$ can play the same role as $u, v$ after changing variables by such a transcendental transformation. These also generate the Weyl algebra which is isomorphic to $W_{\hbar}$. Thus, in a geometrical intuitive mind, $e_{*}^{t i e^{a v} * u}$ is expected to play as if $e_{*}^{t u}$. In the Moyal product formula, we see that $e_{*}^{t u}$ is the ordinary exponential function $e^{t u}$. Hence left-( resp. right-) multiplication $e_{*}^{t u} *$ (resp. $* e_{*}^{t u}$ ) are invertible linear operator on $C^{\infty}(U)$.

It is remarkable that if we take the Fourier transform, the equation (1.2) turns out to be a simple differential equation.

In this paper, we show that the $*$-exponential function $e_{*}^{t i e^{a v} * u}$ is welldefined for all $t \in \mathbb{R}$ and it is real analytic. By the uniqueness of real analytic solutions, we see that $e_{*}^{t i e^{a v} * u}$ satisfies the exponential law:

$$
e_{*}^{(s+t) i e^{a v} * u}=e_{*}^{s i e^{a v} * u} * e_{*}^{t i e^{a v} * u}
$$

However, $e_{*}^{t i e^{a v^{*}} * u}$ behaves very strangely. We show that there are a lot of non-real analytic solutions and the uniqueness does not hold to the positive direction. In spite of this, the uniqueness holds for the negative direction. As a result, we can show the phenomenon of associativity breaking.

Throughout this paper, we concentrate to obtain the concrete formula of

$$
e_{*}^{t i e^{a v} * u}, \quad e_{*}^{t i e^{a v_{* u}} *} * e^{\frac{2 i}{\hbar} u v} \quad \text { and } \quad e_{*}^{t i e^{a v_{*}} * u} * e^{-\frac{2 i}{\hbar} u v},
$$

because it is known that functions $2 e^{\frac{2 i}{\hbar} u v}$ and $2 e^{-\frac{2 i}{\hbar} u v}$ play important roles in the construction of operator representation of our $\mathbb{C}[u, v]$-module. By the Moyal product formula, we see that

$$
v * 2 e^{\frac{2 i}{\hbar} u v}=0, \quad u * 2 e^{-\frac{2 i}{\hbar} u v}=0
$$

but

$$
2 e^{\frac{2 i}{\hbar} u v} * 2 e^{\frac{2 i}{\hbar} u v}=2 e^{\frac{2 i}{\hbar} u v}, \quad 2 e^{-\frac{2 i}{\hbar} u v} * 2 e^{-\frac{2 i}{\hbar} u v}=2 e^{-\frac{2 i}{\hbar} u v}
$$

and

$$
2 e^{\frac{2 i}{h} u v} * 2 e^{-\frac{2 i}{\hbar} u v}=\text { diverge } .
$$

By the formula $u * e^{-\frac{2 i}{\hbar} u v}=0$, we see that

$$
\left(e^{a v} * u\right) * e^{-\frac{2 i}{\hbar} u v}=0 .
$$

Hence, it is natural to expect that $e_{*}^{i t e e^{a v} * u} * e^{-\frac{2 i}{\hbar} u v}=e^{-\frac{2 i}{\hbar} u v}$. Such an identity is obtained as a bi-product of our proof of the main theorem.

## §2. *-exponential function of $e^{a v} * u$

Since $\overline{e^{a v} * u}=u * e^{a v}=e^{a v} *(u-\hbar i a), \quad e^{a v} * u$ is not an hermite element, though $u$ and $v$ are restricted in reals.

Set $L_{t}(g)=F_{t}(u, v)$. Since

$$
i e^{a v} * f(u, v)=i e^{a v} f\left(u+\frac{\hbar i a}{2}, v\right),
$$

we see that (1.2) turns out to be

$$
\partial_{t} F_{t}(u, v)=i e^{a v}\left\{\left(u+\frac{\hbar i a}{2}\right) F_{t}\left(u+\frac{\hbar i a}{2}, v\right)-\frac{\hbar i}{2} \partial_{v} F_{t}\left(u+\frac{\hbar i a}{2}, v\right)\right\},
$$

with initial condition $F_{0}=g(u, v)$. If we set $F_{t}(u, v)=G_{t}(u, v) e^{-\frac{2 i}{\hbar} u v}$, then we have

$$
\begin{equation*}
\partial_{t} G_{t}(u, v)=\frac{\hbar}{2} e^{2 a v} \partial_{v} G_{t}\left(u+\frac{\hbar i a}{2}, v\right) \tag{2.1}
\end{equation*}
$$

with the initial condition $G_{0}=g(u, v) e^{\frac{2 i}{\hbar} u v}$. This is not a differential equation, but an evolution equation of a differential-difference operator.

Real analytic solutions, if they exist, are unique with respect to initial functions. The solution, if exists, might be written as the $*$-exponential function
$e_{*}^{t i e^{a v} * u} * g$, where $g$ is the initial function, and $e_{*}^{t i e^{a v} * u}$ is the real analytic solution with initial function 1.

For the sake of self-containedness, we repeat here the definition of real analyticity. Remark first that $C^{\infty}(U)$ is a Fréchet space whose topology is given by countable seminorms. Let $\mathbb{E}$ be a Fréchet space whose topology is given by countable seminorms $\left\|\|_{k}\right.$. A smooth mapping $f: \mathbb{R} \rightarrow \mathbb{E}$ is real analytic, if for every $\left\|\|_{k}\right.$, and for every $t_{0} \in \mathbb{R}$, the Taylor series at every $t_{0}$ converges in $\left\|\|_{k}\right.$ on some neighborhood of $t_{0}$ which may depend on $k$.

However, if $G_{t}$ is restricted to periodic functions $G_{t}\left(u+\frac{\hbar i a}{2}, v\right)=G_{t}(u, v)$, then (2.1) turns out to be

$$
\left(\partial_{t}-\frac{\hbar}{2} e^{2 a v} \partial_{v}\right) G_{t}(u, v)=0
$$

and the solution is given by

$$
G_{t}(u, v)=\varphi\left(u, \frac{\hbar t}{2}-\frac{1}{2 a} e^{-2 a v}\right)
$$

Thus, if the initial function $G_{0}$ is restricted furthermore to a periodic function $G_{0}\left(u, v+\frac{\pi i}{a}\right)=G_{0}(u, v)$, then the solution is written uniquely by the above shape.

Next, we want to restrict the variables $u, v$ to the real line. To do this, denote by $\mathfrak{S}$ be the space of all rapidly decreasing functions of the variable $\xi$, and let $\mathfrak{S}^{\prime}$ be its dual space, that is the space of all slowly increasing distributions.

First we assume that $G_{t}(u, v)$ is written as

$$
G_{t}(u, v)=\int_{-\infty}^{\infty} a(t, \xi, v) e^{i \xi u} d \xi
$$

by using slowly increasing Schwartz distribution $a(t, \xi, v)$ with respect to $\xi$ (i.e. $a(t, \xi, v)$ is a $\mathfrak{S}^{\prime}$-valued $C^{\infty}$ function). Then the above equation (2.1) is changed into the differential equation

$$
\begin{equation*}
\left(e^{a \hbar \xi / 2} \partial_{t}-\frac{\hbar}{2} e^{2 a v} \partial_{v}\right) a(t, \xi, v)=0 \tag{2.2}
\end{equation*}
$$

It is remarkable that $\xi$ plays only as a parameter. (2.2) shows that $a(t, \xi, v)$ is constant along the real analytic vector field $e^{a \hbar \xi / 2} \partial_{t}-\frac{\hbar}{2} e^{2 a v} \partial_{v}$.

Figure 1: Level curves of $\frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}$
Along the integral curves of this vector field, $\eta=\frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}$ is constant.

Thus, by fixing $\xi$ arbitrarily, and by replacing

$$
t^{\prime}=t-\frac{1}{a \hbar} e^{-2 a v} e^{a \hbar \xi / 2}, \quad v^{\prime}=v,
$$

the identities

$$
\partial_{t^{\prime}}=\partial_{t}, \quad \partial_{v^{\prime}}=-\frac{2}{\hbar} e^{a \hbar \xi / 2} e^{-2 a v} \partial_{t}+\partial_{v}
$$

shows that if $\xi$ is fixed in $\mathbb{R}$, the solutions $a(t, \xi, v)$ are given by arbitrary functions of $t^{\prime}$, not containing $v^{\prime}$. That is, the solutions are given as arbitrary functions of $\frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}$ by multiplying $\frac{\hbar}{2} e^{-a \hbar \xi / 2}$ to both sides.

Our main theorem is as follows:
Theorem 1. If $t \leq 0$ (resp. $t \geq 0$ ), then the equation

$$
\left\{\begin{array} { r l } 
{ \frac { d } { d t } L _ { t } } & { = ( i e ^ { a v } * u ) * L _ { t } , }  \tag{2.3}\\
{ L _ { 0 } } & { = g ( u , v ) , }
\end{array} \quad \text { resp. } \quad \left\{\begin{array}{rl}
\frac{d}{d t} R_{t} & =R_{t} *\left(i e^{a v} * u\right) \\
R_{0} & =g(u, v)
\end{array}\right.\right.
$$

has the unique solution $L_{t}(g)$, (resp. $\left.R_{-t}(g)\right)$ for almost all initial functions $g$ with polynomial growth. However, if $t>0$ (resp. $t<0$ ), then the equation has a solution for almost all initial functions $g$ with polynomial growth, but these are not unique, i.e. $L_{t}, t>0$ is not defined as operators.

Precise definition of "almost all" will be clarified in the proof.

For every $(t, v)$, we may view $a(t, \xi, v)$ as an $\mathfrak{S}^{\prime}$-valued function $a(t, v)(\xi)$, that is for every test function $\psi(\xi) \in \mathfrak{S}$,

$$
\int\left(\partial_{t} a(t, v)(\xi) e^{a \hbar \xi / 2}-\frac{\hbar}{2} e^{2 a v} \partial_{v} a(t, v)(\xi)\right) \psi(\xi) d \xi=0
$$

The solution is written by using a $\mathfrak{S}^{\prime}$-valued $C^{\infty}$ function $\varphi(v)(\xi)=\varphi(\xi, v)$ as

$$
\begin{equation*}
a(t, \xi, v)=\varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right) . \tag{2.4}
\end{equation*}
$$

The right hand side of (2.4) is the distribution defined for the test function $\psi(\xi) \in \mathfrak{S}$

$$
\int \varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right) \psi(\xi) d \xi .
$$

The condition that has been imposed is as follows:
Condition 1. $\varphi(\xi, v)$ is a $\mathfrak{S}^{\prime}$-valued $C^{\infty}$ function such that for every $(t, v)$,

$$
\varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right)
$$

is also a slowly increasing Schwartz distribution.
Let $\mathcal{S}_{u, v}$ be the set of all Fourier image of such functions. In particular, if $\operatorname{supp} \varphi$ is bounded below with respected to $\xi$, then $\varphi$ satisfies the condition.

Setting $t=0$ in (2.4) gives the Fourier inverse image of the initial function. Remark

$$
e^{\frac{c i}{\hbar} u v}=\int_{-\infty}^{\infty} \delta\left(\xi-\frac{c v}{\hbar}\right) e^{i \xi u} d \xi
$$

Then the solution $\varphi$ with initial function $g$ being $e^{\frac{2 i}{\hbar} u v}, 1$ or $e^{-\frac{2 i}{h} u v}$, is given respectively as follows:

$$
\varphi\left(\xi,-\frac{1}{2 a} e^{-2 a v}\right)=\delta\left(\xi-\frac{4 v}{\hbar}\right), \quad \delta\left(\xi-\frac{2 v}{\hbar}\right), \quad \delta(\xi)
$$

In general if $\hat{g}(\xi, v)=\int e^{-i u \xi} g(u, v) đ u$ is the Fourier transform of $g(u, v)$, then the Fourier image of $G_{0}(u, v)=g(u, v) e^{\frac{2 i}{\hbar} u v}$ with respect to the variable $u$ is

$$
\psi(\xi, v)=\int \delta\left(\xi^{\prime}-\frac{2 v}{\hbar}\right) \hat{g}\left(\xi-\xi^{\prime}, v\right) d \xi^{\prime}=\hat{g}\left(\xi-\frac{2 v}{\hbar}, v\right)
$$

and hence

$$
\begin{equation*}
\varphi\left(\xi,-\frac{1}{2 a} e^{-2 a v}\right)=\hat{g}\left(\xi-\frac{2 v}{\hbar}, v\right) . \tag{2.5}
\end{equation*}
$$

Thus the distribution $\varphi(\xi, \eta)$ which gives the initial function $G_{0}(u, v)=$ $e^{\frac{2 i}{\hbar} u v}$ or $G_{0}(u, v)=g(u, v) e^{\frac{2 i}{\hbar} u v}$ is given respectively, by putting $-2 a \eta=e^{-2 a v}$ at the place $\eta \leq 0$, as followings:

$$
\begin{aligned}
& \varphi(\xi, \eta)=\delta\left(\xi+\frac{1}{a \hbar} \log (-2 a \eta)\right), \\
& \varphi(\xi, \eta)=\hat{g}\left(\xi+\frac{1}{a \hbar} \log (-2 a \eta),-\frac{1}{2 a} \log (-2 a \eta)\right)
\end{aligned}
$$

and these are arbitrary where $\eta>0$.
By this, if the initial condition is $F_{0}(u, v)=1$, then the solution is

$$
\begin{equation*}
\varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right)=\delta\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right) \tag{2.6}
\end{equation*}
$$

For the general initial function $F_{0}(u, v)=g(u, v)$, we see

$$
\begin{equation*}
=\hat{g}\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right),-\frac{1}{2 a} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right) . \tag{2.7}
\end{equation*}
$$

In general, if $\eta \geq 0, t$ is always positive $>0$ on the curve defined by $\frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{2 a v}=\eta$ (see Figure 1). So this curve does not cross the initial surface $t=0$.

Since we are trying to fix the solution by means of initial data, this is possible only for $\eta<0$. For $\eta \geq 0, \varphi$ is arbitrary. Hence the solution is not unique.

Remark 2. The family of curves $\frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}=\eta$ is holomorphic. Thus, if $(t, v)$ is complex, then every curve does cross the initial surface $t=0$.

Recall that the solution of (2.2) is given by

$$
a(t, \xi, v)=\varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right),
$$

and the initial data is given as $a(\xi, v)=\varphi\left(\xi,-\frac{1}{2 a} e^{-2 a v}\right)$. Hence, the restriction for the initial data is only that $a(\xi, v)$ has the periodicity $a(\xi, v)=a\left(\xi, v+\frac{\pi i}{a}\right)$.

## §3. The solutions with initial data $1, e^{\frac{2 i}{\hbar} u v}, e^{-\frac{2 i}{\hbar} u v}$

In particular, write the solution $L_{t}(1)$ with initial data 1 by $\tilde{F}_{t}(u, v)$. Then, $\tilde{F}_{t}(u, v)$ is given by

$$
\tilde{F}_{t}(u, v)=e^{-\frac{2 i}{\hbar} u v} \int_{-\infty}^{\infty} \delta\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right) e^{i \xi u} d \xi
$$

For $t \leq 0$, we see that

$$
\xi^{\prime}=\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)
$$

gives a diffeomorphism of $\xi$-space. Thus it is better to change the variable by this diffeomorphism. Since the property of delta function gives $\tilde{G}_{t}(u, v)=$ $\left.e^{i \xi u} \frac{d \xi}{d \xi^{\prime}}\right|_{\xi^{\prime}=0}$, we express this as a function of $u, v$. Since

$$
\frac{d \xi^{\prime}}{d \xi}=1+\frac{1}{2} \frac{a \hbar t e^{-a \hbar \xi / 2}}{e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}}
$$

the point $\xi^{\prime}=0$ is given as the solution of the equation $e^{-a \hbar \xi}+a \hbar t e^{-\frac{a \hbar \xi}{2}}=$ $e^{-2 a v}$. For both $t \leq 0$ and $t>0$, the solution is given by

$$
\begin{equation*}
2 e^{-a \hbar \xi / 2}=-a \hbar t+\sqrt{(a \hbar t)^{2}+4 e^{-2 a v}} . \tag{3.1}
\end{equation*}
$$

We write the right hand side of (3.1) as $\psi$, and

$$
\begin{equation*}
\left.\frac{d \xi^{\prime}}{d \xi}\right|_{\xi^{\prime}=0}=\frac{\psi}{\psi+a \hbar t} \tag{3.2}
\end{equation*}
$$

Thus, we have

$$
\begin{gathered}
\tilde{G}_{t}(u, v)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2} \psi} \frac{\psi}{\psi+a \hbar t}, \\
\tilde{F}_{t}(u, v)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2} \psi} \frac{\psi}{\psi+a \hbar t} e^{-\frac{2 i}{\hbar} u v} .
\end{gathered}
$$

These are real analytic in $(t, v)$. This solution can be extended naturally to the domain $t>0$. It is also easy to check that this is a solution for all $t$ by remarking the following identity:

$$
\begin{gathered}
\tilde{G}_{t}\left(u+\frac{a \hbar i}{2}, v\right)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2} \psi} \frac{\psi^{2}}{2(\psi+a \hbar t)}, \\
\partial_{t} \psi=-a \hbar \frac{\psi}{\psi+a \hbar t}, \quad \partial_{v} \psi=-4 a \frac{e^{-2 a v}}{\psi+a \hbar t} .
\end{gathered}
$$

$\tilde{F}_{t}(u, v)$ is real analytic by its construction.

Lemma 3. For every $s, t \in \mathbb{R}$, the exponential law

$$
\tilde{F}_{s}(u, v) * \tilde{F}_{t}(u, v)=\tilde{F}_{s+t}(u, v)
$$

holds.
We can write $e_{*}^{i t{ }^{a v} * u}=\tilde{F}_{t}(u, v)$ precisely as

$$
\begin{equation*}
\tilde{F}_{t}(u, v)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2} e^{a v} \psi} \frac{e^{a v} \psi}{e^{a v} \psi+e^{a v} a \hbar t}, \quad e^{a v} \psi=-a \hbar t e^{a v}+\sqrt{\left(a \hbar t e^{a v}\right)^{2}+4} \tag{3.3}
\end{equation*}
$$

Moreover,

$$
\begin{align*}
& \sqrt{\left(\frac{1}{2} e^{a v} a \hbar t\right)^{2}+1}+\frac{1}{2} e^{a v} a \hbar t=\left(\sqrt{\left(\frac{1}{2} e^{a v} a \hbar t\right)^{2}+1}-\frac{1}{2} e^{a v} a \hbar t\right)^{-1}  \tag{3.4}\\
& \left(1-\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right)\left(1+\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right)=\frac{4}{\left(e^{a v} a \hbar t\right)^{2}+4} \tag{3.5}
\end{align*}
$$

Remarking above, we see $e^{a v} \psi(-t, v)=a \hbar t e^{a v}+\sqrt{\left(a \hbar t e^{a v}\right)^{2}+4}$ and

$$
\begin{aligned}
\tilde{F}_{-t}(u, v) & =e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2} e^{a v} \psi(-t, v)} \frac{e^{a v} \psi(-t, v)}{e^{a v} \psi(-t, v)-e^{a v} a \hbar t} \\
& =e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2}\left(e^{a v} a \hbar t+\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}\right)}\left(1+\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right) .
\end{aligned}
$$

We have also

$$
\overline{\tilde{F}_{-t}(u, v)}=\tilde{F}_{t}(u, v)\left(\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}+e^{a v} a \hbar t\right)^{2}
$$

The reason why $\tilde{F}_{t}(u, v)$ is not a unitary element is that $e^{a v} * u$ is not hermite and $\overline{e^{a v} * u}=u * e^{a v}$.

Since $e^{a v} * u=e^{a v}\left(u+\frac{a \hbar i}{2}\right)$ and $u * e^{a v}=e^{a v}\left(u-\frac{a \hbar i}{2}\right)$, we have $e^{a v} u=$ $e^{a v} *\left(u-\frac{a \hbar i}{2}\right)$ is an hermite element. Thus, if we replace $u$ by $u+\frac{a \hbar}{2}$ and construct

$$
\hat{F}_{t}(u, v)=e_{*}^{t i\left(e^{a v} u\right)}
$$

then,

$$
\hat{F}_{t}(u, v)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2}\left(-e^{a v} \hbar t+\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}\right.}\left(\frac{2}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right)
$$

It is easy to see that

$$
\overline{\hat{F}_{-t}(u, v)}=\hat{F}_{t}(u, v)
$$

On the other hand, for the original $\tilde{F}_{t}(u, v)$ we can check that the bracket vanishes

$$
\left[e^{a v} * u, e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2}\left(\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}+e^{a v} a \hbar t\right)}\left(1+\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right)\right]=0
$$

by direct computations. By these, we see that

## Proposition 4.

$$
e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2}\left(\sqrt{\left(e^{-2 v} a \hbar t\right)^{2}+4}+e^{a v} a \hbar t\right)}\left(1+\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right)
$$

is the solution of the right equation

$$
\frac{d}{d t} R_{t}=R_{t} *\left(i e^{a v} * u\right), \quad R_{0}=1
$$

3.1. The solution of the initial condition $e^{\frac{2 i}{\hbar} u v}$. The distribution which gives the solution $\varphi$ in (2.4) is given by

$$
\varphi(\xi, \eta)=\delta\left(\xi+\frac{2}{a \hbar} \log (-2 a \eta)\right)
$$

Thus, the solution at the time $t$ is

$$
\varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right)=\delta\left(\xi+\frac{2}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right)
$$

This is similar to (2.6), but since the coefficient is changed from $a \hbar$ to $a \hbar / 2$, the behavior is changed as follows: If $2 \hbar t<1$, then we see

$$
\xi+\frac{2}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)>0
$$

and therefore the right hand side vanishes.
All together, we see the following:
Theorem 5. For every $t \in \mathbb{R}, L_{t}\left(e^{\frac{2 i}{\hbar} u v}\right)$, $L_{t}\left(e^{-\frac{2 i}{\hbar} u v}\right)$ is a real analytic solution in $t$. Moreover, $L_{t}\left(e^{-\frac{2 i}{\hbar} u v}\right)=e^{-\frac{2 i}{\hbar} u v}$ and $L_{t}\left(e^{\frac{2 i}{\hbar} u v}\right)=0$ for $2 \hbar t \leq 1$.

Proof. For initial functions $e^{\frac{2 i}{\hbar} u v}$ and $e^{-\frac{2 i}{\hbar} u v}$, these Fourier images are $\delta\left(\xi-\frac{4 v}{\hbar}\right)$ and $\delta(\xi)$. They satisfy the Condition 1.

The first one is obtained by viewing the equation as the equation of vector field $\left(e^{a v} * u\right) * e^{-\frac{2 i}{\hbar} u v}=0$. Actually this is obtained by the fact that the initial function is $\varphi(\xi, \eta)=\delta(\xi)$ (cf. (3.6)).

The relation $\left[\frac{1}{a} e^{-a v}, e^{a v} * u\right]=-\hbar i$ gives the following:
Proposition 6. Let

$$
\tilde{F}_{t}(u, v)=e^{-\frac{2 i u}{a \hbar} \log \frac{1}{2}\left(\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}-e^{a v} a \hbar t\right)}\left(1-\frac{e^{a v} a \hbar t}{\sqrt{\left(e^{a v} a \hbar t\right)^{2}+4}}\right),
$$

then

$$
\left[\frac{1}{a \hbar} e^{-a v}, \tilde{F}_{s}(u, v)\right]=s \tilde{F}_{s}(u, v)
$$

Proof. At $t=0$, we have $\left[e^{-a v}, \tilde{F}_{0}(u, v)\right]=0$. Taking the derivative

$$
\begin{aligned}
\frac{d}{d t}\left[\frac{1}{a} e^{-a v}, \tilde{F}_{t}(u, v)\right] & =\left[\frac{1}{a} e^{-a v}, i e^{a v} * u * \tilde{F}_{t}(u, v)\right] \\
& =\hbar \tilde{F}_{t}(u, v)+i e^{a v} * u *\left[\frac{1}{a} e^{-a v}, \tilde{F}_{t}(u, v)\right]
\end{aligned}
$$

Set $\left[\frac{1}{a} e^{-a v}, \tilde{F}_{t}(u, v)\right]=\tilde{F}_{t}(u, v) * g_{t}$ and looking for the solution, then $\tilde{F}_{t}(u, v) *$ $\frac{d}{d t} g_{t}=\hbar \tilde{F}_{t}(u, v)$ gives $\hbar t \tilde{F}_{t}(u, v)$ is a real analytic solution. However, this does not give the uniqueness. This is given by the direct calculation: Since

$$
\left[e^{-a v}, \tilde{F}_{t}(u, v)\right]=e^{-a v}\left(\tilde{F}_{t}\left(u-\frac{\hbar i a}{2}, v\right)-\tilde{F}_{t}\left(u+\frac{\hbar i a}{2}, v\right)\right)
$$

(3.4) gives that the result.

Rewriting the above, for $\left(e^{-a v}-a \hbar s\right) * \tilde{F}_{s}=\tilde{F}_{s} * e^{-a v}$, then, we have the following.

Lemma 7. If $s \geq 0$,

$$
\begin{aligned}
\tilde{F}_{-s}(u, v) *\left(e^{-a v} * \tilde{F}_{s}(u, v)\right)-a \hbar s & =\tilde{F}_{-s}(u, v) *\left(\left(e^{-a v}-a \hbar s\right) * \tilde{F}_{s}(u, v)\right) \\
& =\tilde{F}_{-s}(u, v) *\left(\tilde{F}_{s}(u, v) * e^{-a v}\right)=e^{-a v} .
\end{aligned}
$$

Proof. $\tilde{F}_{s}(u, v) * e^{-a v}$ is defined and the solution of left equation with the initial function $e^{-a v}$. The first equality is given by the distributive law and the exponential law. On the other hand, for $t \geq 0$ the uniqueness for the left equation, the exponential law gives $\tilde{F}_{-t}(u, v) *\left(\tilde{F}_{s}(u, v) * g\right)=\tilde{F}_{-t+s}(u, v) * g$. Then, set $t=s$.

This is indeed a dangerous equality. If the associativity holds then, applying $F_{s}$ and $F_{-s}$ to both side from left and right, we see that the above formula is valid for $s<0$. It follows

$$
1=\left(F_{-s} * e^{a v} * F_{s}\right) *\left(F_{-s} * e^{-a v} * F_{s}\right)=\left(F_{s} * e^{a v} * F_{-s}\right) *\left(e^{-a v}+a \hbar s\right)
$$

and hence $e^{-a v}+a \hbar s$ is invertible for $s<0$. This makes contradiction. Thus, we see that the associativity must break at some point.

We want to see how the associativity breaks down.
3.2. For general initial functions. For a general initial function $g$, the solution for $t \leq 0$ is given by (2.7) and this is

$$
\begin{aligned}
& G_{t}(u, v) \\
& =\int e^{i \xi u} \hat{g}\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right),-\frac{1}{2 a} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right) d \xi
\end{aligned}
$$

This is determined uniquely by $g$. Denote this by $\tilde{L}_{t}(g)(t \leq 0)$. The real analyticity in $t$ does not hold unless $g$ has some smooth property. But for $t \leq 0, \tilde{L}_{t}$ is a linear operator of $\mathcal{S}_{u, v}$ into $\mathcal{S}_{u, v}$.

For $t>0$, there is a place such that $e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}<0$. In such a place the solution is not determined by the initial function $g$, but $\varphi$ may be chosen arbitrarily so that $G_{t}(u, v)$ is $C^{\infty}$. This implies that for $t>0$ the uniqueness does not hold for the left equation.

Avoiding this inconvenience, we fix the solution. One way to fix the solution is that we set $\varphi(\xi, \eta)=0$ for $\eta>0$.

This means we set to 0 on the domain $e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}<0$. Here $G_{t}(u, v)$ must be $C^{\infty}$. For this we must have that

$$
\begin{aligned}
& \int \varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right) e^{i \xi u} d \xi \\
& =\int_{-\infty}^{\frac{2}{a \hbar} \log (a \hbar t)-\frac{1}{\hbar} 4 v} \varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right) e^{i \xi u} d \xi
\end{aligned}
$$

is $C^{\infty}$ function and this looks like a new condition. But the imposed condition is in fact that this must be a slowly increasing distribution for every fixed $t, v$. Hence the $C^{\infty}$-ness in $t, v$ is satisfied automatically.

Thus, if we set

$$
\begin{align*}
& \varphi_{0}\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right)  \tag{3.6}\\
= & \left\{\begin{array}{lr}
\hat{g}\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right),-\frac{1}{2 a} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right) \\
& \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}>0\right) \\
0, & \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2} \leq 0\right),
\end{array}\right.
\end{align*}
$$

then we have the solution for $t>0$. Write this by $L_{t}(g)$. The second line of (3.6) may not be used if $\lim _{v \rightarrow \infty} g(\xi, v)=0$. Thus, $L_{t}(g)$ is defined for all $g \in \mathcal{S}_{u, v}$. For $t \geq 0$, it is clear that $L_{t}(g)=\tilde{L}_{t}(g)$.

In any way, for every initial function $g(u, v) \in \mathcal{S}_{u, v}$, the solution of the equation (2.3) is defined for all $t \in \mathbb{R}$.

The direct calculation shows this is a solution. This proved Theorem 1.
$L_{t}$ for $t>0$ is by the equality (3.6) has the property that $L_{t}(g)=0$ means $g=0$. That is to say $L_{t}: \mathcal{S}_{u, v} \rightarrow \mathcal{S}_{u, v}$ is a monomorphism for $t \geq 0$.

However there are other solutions, and the uniqueness does not hold. For $t>0, L_{t}(g)=\tilde{F}_{t} * g$ may not hold. Such identity holds only for $t \leq 0$.

The above observation tells us many: For $t \geq 0, \tilde{L}_{-t}(g)$ is determined by $g$. If we denote by $g_{t}$ a solution with initial function $g$, then $\tilde{L}_{-t}\left(g_{t}\right)=g$ holds.

We have many $g_{t}$. Hence the linearity of the left equation gives for $t>0$ that $\tilde{L}_{-t}$ has the non trivial kernel $\left(\tilde{L}_{-t}(K)=0\right) . \tilde{L}_{-t}(K)$ may be written as $\tilde{L}_{-t}(1) * K, \tilde{F}_{t}=\tilde{L}_{t}(1)$ and the exponential law holds for $\tilde{F}_{t}$. Since $\tilde{F}_{t} * \tilde{F}_{-t}=1$, $0=\tilde{F}_{t} *\left(\tilde{F}_{-t} * K\right) \neq K$ shows that the associativity breaks down at such place.

Lemma 8. $\tilde{L}_{-t}: \mathcal{S}_{u, v} \rightarrow \mathcal{S}_{u, v}$ has non-trivial kernel for $t>0$, and $\tilde{L}_{-t} L_{t}=I$.
3.3. Ker $\tilde{L}_{t}$. For $t \leq 0, \tilde{L}_{t}(g)$ is uniquely determined for initial functions. Here we consider the case $t<0$. Recall (3.3) at first. In (3.6) the initial function $\hat{g}(\xi, v)$ satisfies for some $t<0$ that

$$
\begin{align*}
& \varphi\left(\xi, \frac{\hbar t}{2} e^{-a \hbar \xi / 2}-\frac{1}{2 a} e^{-2 a v}\right)  \tag{3.7}\\
& \quad=\hat{g}\left(\xi+\frac{1}{a \hbar} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right),-\frac{1}{2 a} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right)=0 .
\end{align*}
$$

Let $G(u, v)=\int \hat{g}(\xi, v) e^{i \xi u} d \xi$ be the initial function corresponding to $\hat{g}(\xi, v)$. Then setting $K(u, v)=G(u, v) e^{-\frac{2 i}{\hbar} u v}$, we see that $L_{t}(K)=\tilde{F}_{t}(u, v) * K=0$.

We want to characterize $\hat{g}(\xi, v)$. Fix $t<0$ and we first determine the domain

$$
\begin{equation*}
E_{t}=\left\{\left(\xi+\frac{1}{\hbar} \mu,-\frac{1}{2} \mu\right) \left\lvert\, \mu=\frac{1}{a} \log \left(e^{-2 a v}-a \hbar t e^{-a \hbar \xi / 2}\right)\right., \xi, v \in \mathbb{R}\right\} . \tag{3.8}
\end{equation*}
$$

If the supp $\hat{g}$ is in the complement of $E_{t}, \hat{g}$ satisfies this condition.
If $t<0$ is fixed, the above $\mu$ in (3.8) moves in the range $\mu>\log \left(-a \hbar t e^{-a \hbar \xi / 2}\right)$ for every $\xi$, since $e^{-2 a v}$ takes arbitrary positive number, By this, we see

$$
E_{t}=\left\{(\xi, \eta) \left\lvert\, \eta<\frac{\hbar}{2} \xi-\frac{1}{a} \log (-a \hbar t)\right.\right\} .
$$

A distribution, supported in $D_{t}=E_{t}^{c}$ and satisfying Condition 1, satisfies also (3.7). In particular for every $\eta$ this must be a slowly increasing distribution with respect to $\xi$. By the property of the domain $D_{t}$, it is finite for the direction $\xi>0$. If $0 \geq t>t^{\prime}, D_{t} \subset D_{t^{\prime}}$ is clear.

Initial function $\hat{g}(\xi, v)$ reflects $\tilde{L}_{t}(g)$ at $t<0$ only for the part $(\xi, v) \in E_{t}$.
Proposition 9. For $\hat{g}(\xi, v)$, if $\operatorname{supp} \hat{g} \subset D_{t}, t<0$, Setting

$$
G(u, v)=\int \hat{g}(\xi, v) e^{i \xi u} d \xi, \quad K(u, v)=G(u, v) e^{-\frac{2 i}{\hbar} u v}
$$

we have $L_{t}(K)=\tilde{F}_{t}(u, v) * K=0$.
