We consider the bifurcation problem

$$\begin{aligned} -u''(t) &= \lambda\left(u(t)+g(u(t))\right), \quad x \in I := (-1,1), \\ u(t) &> 0, \quad t \in I, \\ u(-1) &= u(1) = 0. \end{aligned}$$

Here, $\lambda > 0$ is a bifurcation parameter. The typical example of $g(u)$ is $g_1(u) := \sin\sqrt{u}$. It is well known that under the suitable conditions on $g(u)$, λ is parameterized by the maximum norm $\alpha = \|u_\lambda\|_\infty$ of the solution u_λ corresponding to λ and is written as $\lambda = \lambda(g,\alpha)$. It should be mentioned that if $g(u) = g_1(u) = \sin\sqrt{u}$, then this problem has been proposed in Cheng (2002) as an example which has arbitrary many solutions near the line $\lambda = \pi^2/4$. In this talk, we first show that the bifurcation diagram of $\lambda(g_1,\alpha)$ intersects the line $\lambda = \pi^2/4$ infinitely many times by establishing the precise asymptotic formulas for $\lambda(g_1,\alpha)$ as $\alpha \to \infty$. Secondly, we generalize the results above and treat the other cases, which produce the bifurcation curves intersecting the line $\lambda = \pi^2/4$ infinitely many times.
