Abstract. An enhanced algorithm and the computational results on the classification of two-symbol orthogonal arrays of strength 2, size 24, 6 constraints and index 6 derivable from 130 representatives of saturated orthogonal arrays having maximal constraints are given. A table of 1,317 representative 2-OA(2,6,6)'s obtained is given by indicating the selected set of 6 columns of a representative saturated array of 23 constraints each.

Key words and phrases. Orthogonal array, factorial design.

§0. Introduction

Orthogonal 2^m factorial designs have widely been used in factor screening and related experiments. Among others, such designs obtained by assigning factors to the appropriate columns of a saturated orthogonal array, or an array having maximal constraints, have been recommended for practical use (see, e.g., Taguchi [6,7], Box and Hunter [1,2], Hedayat [3], Namikawa, Fujii and Yamamoto [5] and Yamamoto, Fujii, Hyodo and Yumiba [10]). Such kind of saturated orthogonal arrays, however, have been restricted to those constructed by the standard orthogonal polynomial models. Moreover, the

size or the number of runs of such a design is necessarily restricted to the power of two.

All of the saturated orthogonal arrays of size 4λ are isomorphic to each other with respect to the permutation of $4\lambda - 1$ columns (factors) and symbols (levels) in each case of $\lambda = 1, 2$ and 3 , respectively. There are, however, several isomorphic classes since Hadamard matrices of size 4λ which are not isomorphic to each other do exist for those integral $\lambda \geq 4$. In fact, as it has been shown in our previous papers (Yamamoto, Fujii, Hyodo and Yumiba [8,9,13]), there are 5, 3 and 130 isomorphic classes of orthogonal arrays in those cases of $\lambda = 4, 5$ and 6 , respectively. The possibility, therefore, of obtaining so many useful orthogonal 2^m factorial designs from such saturated orthogonal arrays is expected as it has been illustrated in our preceding paper (Yamamoto, Fujii, Hyodo and Yumiba [11]). The results of the classification of two-symbol orthogonal arrays of size 16 and 20, and 5 and 6 constraints derivable from representative saturated orthogonal arrays of size 16 and 20 with respect to the permutation of columns and symbols within columns have been given in Yamamoto, Fujii, Hyodo and Yumiba [12]. The same with respect to the arrays of size 24 and 5 constraints is given in Yamamoto, Fujii, Hyodo and Yumiba [14].

In this paper, an enhanced algorithm and the results of the classification of all two-symbol orthogonal arrays of size 24, 6 constraints and index 6 derivable from 130 representatives of saturated orthogonal arrays of strength 2, size 24, 23 (maximal) constraints and index 6 are given.

§1. Orthogonal arrays and modular vectors

An $N \times m$ array of two symbols 0 and 1 is said to be a two-symbol *orthogonal array* of strength t , size N , m constraints and index λ and is denoted by $2\text{-OA}(t, m, \lambda)$ if every $N \times t$ subarray contains all possible $1 \times t$ binary row vectors with the same frequency λ . Note that the order of the arrangement of rows is immaterial in an orthogonal array. An orthogonal array is said to be *isomorphic* to the other if one can obtain from the other by permuting columns and symbols within columns.

Let T be a two-symbol orthogonal array of strength 2, i.e., $2\text{-OA}(2, m, \lambda)$ of size $N = 4\lambda$, and suppose $(j_1^{(\alpha)}, j_2^{(\alpha)}, \dots, j_m^{(\alpha)})$ be its α th row with $j_p^{(\alpha)} = 1$ or 0 for $p = 1, 2, \dots, m$ and $\alpha = 1, 2, \dots, N$.

If the α th row of T is considered to be a binary number of m figures, a decimal number $b_\alpha^* = \sum_{p=1}^m 2^{m-p} j_p^{(\alpha)}$ may be associated to the row for every $\alpha = 1, 2, \dots, N$. Arranging b_α^* in the order of α , a faithful representation vector, i.e.,

$$B^*(T) = [b_1^*, b_2^*, \dots, b_N^*],$$

of T can be constructed.

Rearranging those components of $B^*(T)$ in their order of magnitudes, a vector $B(T)$ which may be called the modular vector of T , i.e.,

$$B(T) = [b_1, b_2, \dots, b_N], \quad b_i \leq b_j \text{ for all } i < j,$$

can be constructed.

Clearly, the correspondence between an orthogonal array T and its modular vector $B(T)$ is one to one.

§2. Essentials of the classification algorithm

Consider all two-symbol orthogonal arrays, 2-OA($2, m, \lambda$)'s of size $N = 4\lambda$, which are derivable from saturated orthogonal arrays, 2-OA($2, N - 1, \lambda$)'s, by selecting sets of m columns. In order to classify those orthogonal arrays into isomorphic classes with respect to the permutation of columns and symbols within columns, it is sufficient to classify those derivable from the $\nu(\lambda)$ representatives of all isomorphic classes of saturated 2-OA($2, N - 1, \lambda$)'s. Here, $\nu(\lambda)$ denotes the number of isomorphic classes of saturated 2-OA($2, N - 1, \lambda$)'s.

The essentials of the algorithm for the classification of those orthogonal arrays with respect to the permutation of columns and symbols within columns are as follows:

Step 1. Get a representative saturated 2-OA($2, N - 1, \lambda$) of size $N = 4\lambda$ labeled by a loop parameter a_k ($1 \leq a_k \leq \nu(\lambda)$) indicating serially the numbers of representative saturated two-symbol orthogonal arrays. If the loop parameter moves up to $a_k > \nu(\lambda)$, the classification process is terminated.

Step 2. Select a set $\{i_1, i_2, \dots, i_m\}$ of m columns ($1 \leq i_1 < i_2 < \dots < i_m \leq N - 1$) of the representative 2-OA($2, N - 1, \lambda$) using i_p 's ($1 \leq p \leq m$) as m -fold nested loop parameters and construct a 2-OA($2, m, \lambda$) composed of the selected m columns. If the first loop parameter moves up to $i_1 > N - m$, the selection process is terminated and go to Step 1 after setting $a_k \leftarrow a_k + 1$.

Step 3. Applying the symbol and column permutation to the constructed 2-OA($2, m, \lambda$), compute the modular vector of the permuted array and search whether the same is already registered in the RF-file or not step by step until the answer becomes affirmative. Here, the RF-file is that of the modular vectors of the representatives of isomorphic classes of 2-OA($2, m, \lambda$).

Step 4. If the answer in Step 3 is affirmative, the symbol and column permutation will be terminated and go to Step 2. While, if the answer is not affirmative until the end of the symbol and column permutation, the modular vector of originally selected 2-OA($2, m, \lambda$) will be registered to the RF-file of 2-OA($2, m, \lambda$) and go to Step 2.

§3. Two remarks on Step 2

Since we can provide the representative saturated two-symbol orthogonal arrays to be those having $(1, 1, \dots, 1)$ in their first row, the number of symbol permutations to be executed may be reduced from 2^m to N which preserve the presence of the row $(1, 1, \dots, 1)$ if $2^m > N$, e.g., from 64 to 24 in the case $\lambda = 6$ and $m = 6$.

The other remark concerns with the method of searching and storing the array with respect to the RF-file. The method of sequential search, that of binary search, etc., are applicable for such purpose. In our case, however, the size (or number of records) of the RF-file to be constructed grows up step by step during the classification process. The method of key (array) to address transformation by hashing for searching and storing the array, which does not depend on the size of the file, is, therefore, preferable in this case. If the final size of RF can be estimated to some extent, it will be helpful in selecting the better function for hashing (see, e.g., Knuth [4]).

The modular vector $B(T)$ of an array T can be considered to be a 2^m -ary number of $N - 1$ figures, i.e.,

$$(b_1 b_2 \dots b_{N-1})_{2^m} = \sum_{i=1}^{N-1} b_i (2^m)^{N-i-1} (= c(T)),$$

since b_N can be disregarded for all arrays considered here. Clearly, T , $B(T)$ and the decimal number $c(T)$ are one to one to each other.

Let $h(B(T))$ be a hash function of the key $B(T)$ to the address defined by

$$h(B(T)) = c(T) \bmod p = c(T) - p \cdot [c(T)/p],$$

which satisfies $0 \leq h(B(T)) \leq p - 1$ for some appropriately chosen prime number p , where $[x]$ denotes the greatest integer not exceeding x .

Except some cases of small m and λ , the number $c(T)$ is too large to handle in the usual computer system. The hash function $h(B(T))$ for a $c(T)$ can, however, be evaluated recursively by calculating $(2^m)^i \bmod p$ as follows:

$$(2^m)^{i+1} \bmod p = 2^m \{(2^m)^i \bmod p\} \bmod p.$$

This makes us possible to evaluate $h(B(T))$ in the usual computer system.

§4. Use of the intermediate file

Applying the algorithm given in Section 2, those results given in Yamamoto, Fujii, Hyodo and Yumiba [12,14] can be obtained easily. This algorithm, however, is not so effective in the case $m = 6$ and $\lambda = 6$, i.e., in the

classification of all 2-OA(2,6,6) ($\binom{23}{6} \times 130 := 1.3 \times 10^7$ in all) derivable from 130 representative 2-OA(2,23,6). A crude estimate obtained after running on the DECstation 5000/125 about 3 months, it seems to take about 1 year and half running in order to get a complete answer of the classification. In view of the fact, the application of the column and symbol permutation group in Step 3 is limited to a subgroup in order to get the affirmative answer as earlier stage of permutation as possible, since the size of the intermediate file of the representatives (IRF-file) may increase considerably by duplicated registration of final representatives in the RF-file.

In our case, a product of two column transpositions, (1,2) and (3,4), has been applied instead of the column permutation of order $6!$. In this case, the final size of the IRF-file has been reduced to about 1.7×10^5 and it took about 2.8 days running to get the file.

Using the IRF-file and applying the algorithm of the classification in Section 2, the RF-file has been constructed. It took only about 5.7 days running in our DECstation 5000/125 system. The final size of the RF-file obtained amounts to 1,317.

§5. Results obtained on the classification of 2-OA(2,6,6)

Those representative arrays of 1,317 isomorphic classes are given in Table 1 by indicating respectively the selected set of 6 columns of the generating saturated orthogonal array. Note that precise number of isomorphic classes of all 2-OA(2,6,6) may or may not be greater than 1,317. A table of 18 saturated arrays of 23 constraints among 130 representatives (Yamamoto, Fujii, Hyodo and Yumiba [13]) which are sufficient to derive those 1,317 arrays is given in Appendix.

Table 1. Representative arrays of 1,317 isomorphic classes of
2-OA(2,6,6)

x: Serial number of representative 2-OA(2,6,6)
